

**Purpose of the Project:** The purpose of this assignment is to write a program to implement autocomplete for a given set of N strings and nonnegative weights. That is, given a prefix, find all strings in the set that start with the prefix, in descending order of weight.

**Submitting Information:**

- Use the code I provided for each problem. DON'T DELETE ANY METHOD
- Put all files in one .zip folder.
- Submit your work on Canvas.
- The deadline is **Monday, Nov 9<sup>th</sup> at 6:00PM**
- Follow the guidelines of the corner cases and performance requirements
- To compile the files, use javac-algs4, to run the files, use java-algs4
- Files to Submit: Term.java, BinarySearchDeluxe.java, Autocomplete.java

**What is Autocomplete:** Autocomplete is an important feature of many modern applications. As the user types, the program predicts the complete query (typically a word or phrase) that the user intends to type. Autocomplete is most effective when there are a limited number of likely queries. For example, the Internet Movie Database uses it to display the names of movies as the user types; search engines use it to display suggestions as the user enters web search queries; cell phones use it to speed up text input.

In these examples, the application predicts how likely it is that the user is typing each query and presents to the user a list of the top-matching queries, in descending order of weight. These weights are determined by historical data, such as box office revenue for movies, frequencies of search queries from other Google users, or the typing history of a cell phone user. For the purposes of this

assignment, you will have access to a set of all possible queries and associated weights (and these queries and weights will not change).

In this assignment, you will implement autocomplete by sorting the queries in lexicographic order; using binary search to find the set of queries that start with a given prefix; and sorting the matching queries in descending order by weight.

**Problem1.** (*Autocomplete Term*) Implement an immutable comparable data type `Term` in `Term.java` that represents an autocomplete term: a string query and an associated real-valued weight. You must implement the following API, which supports comparing terms by three different orders: lexicographic order by query string (the natural order); in descending order by weight (an alternate order); and lexicographic order by query string but using only the first  $r$  characters (a family of alternate orderings). The last order may seem a bit odd, but you will use it in Problem 3 to find all terms that start with a given prefix (of length  $r$ ).

method	description
<code>Term(String query)</code>	initializes a term with the given query string and zero weight
<code>Term(String query, long weight)</code>	initializes a term with the given query string and weight
<code>static Comparator&lt;Term&gt; byReverseWeightOrder()</code>	compares the terms in descending order by weight
<code>static Comparator&lt;Term&gt; byPrefixOrder(int r)</code>	compares the terms in lexicographic order but using only the first $r$ characters of each query
<code>int compareTo(Term that)</code>	compares the terms in lexicographic order by query
<code>String toString()</code>	returns a string representation of the term

*Corner cases.* The constructor should throw a `java.lang.NullPointerException` if query is null and a `java.lang.IllegalArgumentException` if weight is negative.

The `byPrefixOrder()` method should throw a `java.lang.IllegalArgumentException` if  $r$  is negative.

*Performance requirements.* The string comparison functions should take time proportional to the number of characters needed to resolve the comparison.

```
$ java Term data/cities.txt 5
Top 5 by lexicographic order:
2200      's Gravenmoer, Netherlands
19190     's-Gravenzande, Netherlands
134520    's-Hertogenbosch, Netherlands
3628      't Hofke, Netherlands
246056    A Coru a, Spain
Top 5 by reverse-weight order:
14608512      Shanghai, China
13076300      Buenos Aires, Argentina
12691836      Mumbai, India
12294193      Mexico City, Distrito Federal, Mexico
11624219      Karachi, Pakistan
```

**Problem 2. (*Binary Search Deluxe*)** When binary searching a sorted array that contains more than one key equal to the search key, the client may want to know the index of either the first or the last such key. Accordingly, implement a library of static methods `BinarySearchDeluxe.java` with the following API:

method	description
<code>static &lt;Key&gt; int firstIndexOf(Key[] a, Key key, Comparator&lt;Key&gt; comparator)</code>	returns the index of the first key in <code>a[]</code> that equals the search key, or -1 if no such key
<code>static &lt;Key&gt; int lastIndexOf(Key[] a, Key key, Comparator&lt;Key&gt; comparator)</code>	returns the index of the last key in <code>a[]</code> that equals the search key, or -1 if no such key

*Corner cases.* Each static method should throw a `java.lang.NullPointerException` if any of its arguments is null. You should assume that the argument array is in sorted order (with respect to the supplied comparator).

*Performance requirements.* The `firstIndexOf()` and `lastIndexOf()` methods should make at most  $1 + \lceil \log N \rceil$  compares in the worst case, where  $N$  is the length of the array. In this context, a compare is one call to `comparator.compare()`

```
$ java BinarySearchDeluxe data/wiktionary.txt cook
3
```

**Problem 3. (*Autocomplete*)** In this part, you will implement a data type that provides autocomplete functionality for a given set of string and weights, using `Term` and `BinarySearchDeluxe`. To do so, sort the terms in lexicographic order; use binary search to find the set of terms that start with

a given prefix; and sort the matching terms in descending order by weight. Organize your program by creating an immutable data type Autocomplete in `Autocomplete.java` with the following API:

method	description
<code>Autocomplete(Term[] terms)</code>	initializes the data structure from the given array of terms
<code>Term[] allMatches(String prefix)</code>	returns all terms that start with the given prefix, in descending order of weight
<code>int numberOfMatches(String prefix)</code>	returns the number of terms that start with the given prefix

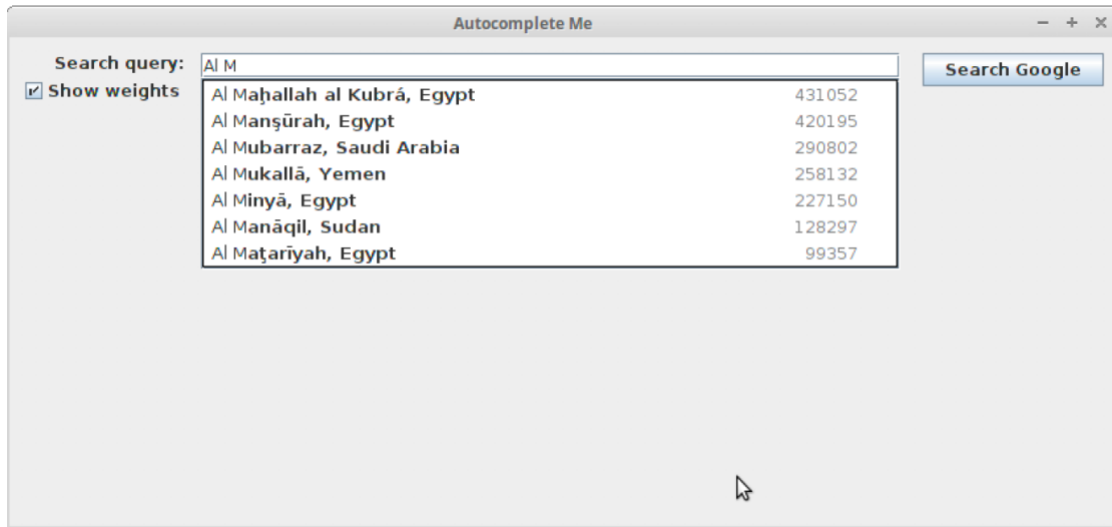

*Corner cases.* The constructor and each method should throw a `java.lang.NullPointerException` if its argument is null.

*Performance requirements.* The constructor should make proportional to  $N \log N$  compares (or better) in the worst case, where  $N$  is the number of terms. The `allMatches()` method should make proportional to  $\log N + M \log M$  compares (or better) in the worst case, where  $M$  is the number of matching terms. The `numberOfMatches()` method should make proportional to  $\log N$  compares (or better) in the worst case. In this context, a compare is one call to any of the `compare()` or `compareTo()` methods defined in `Term`.

```
$ java Autocomplete data/cities.txt 7

128297  Al Man qil , Sudan
99357   Al Ma ar yah , Egypt
<ctrl-d>
```

**Interactive GUI.** The program `AutocompleteGUI` takes the name of a file and an integer  $k$  as command-line arguments and provides a GUI for the user to enter queries. It presents the top  $k$  matching terms in real time. When the user selects a term, the GUI opens up the results from a Google search for that term in a browser.

```
$ java AutocompleteGUI cities.txt 7
```

**Data** Under the **data** directory, we provide sample input files for testing. Each file consists of an integer  $N$  followed by  $N$  pairs of query strings and nonnegative weights. There is one pair per line, with the weight and string separated by a tab. A weight can be any integer between 0 and  $2^{63}-1$ . A query string can be an arbitrary sequence of Unicode characters, including spaces (but not newlines). For example, `wiktionary.txt` contains the 10,000 most common words in Project Gutenberg, with weights proportional to their frequencies.

```
$ more wiktionary.txt
10000
5627187200    the
3395006400    of
2994418400    and
2595609600    to
